INTRODUCTION

Put Introduction here

While the Internet has brought convenience to many people for exchanging information, it also provides opportunities to carry malicious behavior such as online fraud on massive scale with a little cost to the attackers. The attackers can manipulate the Internet users instead of computer system (hardware or software) that significantly increase the barriers of technological crime impact. Such human centered attacks could be done by social engineering. Phishing is a form of social engineering that aims to retrieve credential from online users by mimicking trustworthy and legitimate institutions [28]. These fraudulent attacks are most frequently done by electronic communication such as emails to direct users to fake websites and prompt for sensitive information.

This chapter provides an overview to phishing modus operandi and its current countermeasures such as detection and prevention techniques along with a brief exploration of direct and indirect cost of phishing attacks.

2.1 WHAT IS PHISHING?

Phishing has a similar basic principle as ‘fishing’ in the physical world. Instead of fish, online users are lured by authentic looking communication and hooked by authentic looking websites. Not only that, online users also may be lured by respond to a phishing email, either replying or clicking an obfuscated link within its content. According to Oxford dictionary, the definition of phishing is

a fraudulent practice of sending emails purporting to be from reputable companies in order to induce individuals to reveal personal information, such as passwords and credit card numbers, online [13].

Phishing attack also is a form of online criminal activity by using social engineering techniques [28]. An individual or a group who uses this technique is called *Phisher(s)*. After successfully gaining a sensitive information from the victim, phishers use this information to access victim’s financial accounts or committing credit card frauds. The technique of phishing may vary, but the most common technique of phishing attacks done by using fraudulent emails and websites [29]. A fraudulent website is designed in such a way that it may be identical to its legitimate target. While it may be true, phishing website also could be completely different with its target as there

is no level of identicalness. However, Preliminary analysis on what changed or added in phishing website would be conducted in the later section.

2.1.1 *History of phishing*

The first time the term "phishing" was published by the American Online (AOL) UseNet Newsgroup on January 2, 1996 and was started to expand in 2004 [58]. Since then, we considered phishing development in cyberspace has been flourishing by phishers to make profit. Total losses due to phishing in 2004 reached more than U.S. \$ 2 billion, it was involving more than 15,000 sites that become victims [19]. We will try to discuss about direct and indirect cost at present days in the later section. Evidently, Jakobsson, et al. [28] mentioned that in the early years of 90's (according to [58] it was around 1995) many hackers would create bogus AOL user accounts with automatically generated fraudulent credit card information. Their intention to give this fake credit card information was to simply pass the validity tests performed by AOL. By the time the tests were passed, AOL was thinking that these accounts were legitimate and resulted to activate them. Consequently, these hackers could freely access AOL resources until AOL tried to actually bill the credit card. AOL realized that these accounts were using invalid billing information, thus deactivated the account.

While creating false AOL user accounts with fake credit card information was not exactly phishing attacks, but AOL's effort to counter against the attacks was leading to development of phishing. This countermeasure includes directly verifying the legitimacy of credit card information and the associated billing identity, forced hackers to pursue alternative way [28]. Hackers were masquerading as AOL's employees asking to other users for credit card information through AOL instant messenger and email system [58]. Jakobsson et al. suggest that phishing attacks were originating from this incident [28]. Since such attack has not been done before, many of users have been victimized by then. Eventually, AOL enforced warning system to the most of its customers to be vigilant when it comes to sensitive information [58]. At the present day, phishing attacks might not only being motivated by financial gain but also political reason, and they have been emerging not only aim to AOL users, but also any online users. Consequently, large number of legitimate institutions such as PayPal and eBay are being spoofed.

2.1.2 *Formal definition of phishing*

Before we begin to understand deeper about how and why phishing attack works, we will briefly explore common phishing definition.

Currently, there is no consensus definition, since almost in every research papers, academic textbook or journals has its own definition of phishing [28, 29, 65, 7, 56, 27, 12]. Phishing is also constantly evolving, so it might be very challenging to define its universal terminology. There is not so much study that specifically addresses the standard of phishing definition. However, one research conducted by Lastdrager [36] addressed to achieve consensual definition of phishing. Before we comply with one consensual phishing terminology, we will take a look at various phishing definitions from other sources:

“Phishing is the act of sending a forged e-mail (using a bulk mailer) to a recipient, falsely mimicking a legitimate establishment in an attempt to scam the recipient into divulging private information such as credit card numbers or bank account passwords” [29]

“Phishing is a form of Internet scam in which the attackers try to trick consumers into divulging sensitive personal information. The techniques usually involve fraudulent E-mail and web sites that impersonate both legitimate E-mail and web sites” [65]

“Phishing is an attack in which victims are lured by official looking email to a fraudulent website that appears to be that of a legitimate service provider” [7]

“In phishing, an automated form of social engineering, criminals use the internet to fraudulently extract sensitive information from businesses and individuals, often by impersonating legitimate web sites” [56]

It is noteworthy that the definition described by James, et al, Tally, et al, and Clayton, et al. [29, 65, 7] specifies that the phishers only use email as a communication channel to trick potential victims. While it might be true because using email would greatly cost effective, but we believe that phishing is not only characterized by one particular technological mean, as phishers can also use any other electronic communication to trick potential victims (i.e private message on online social network). This definition is also similar to dictionary libraries [13, 14, 67] that mention email as a medium communication between phishers and users.

We believe that standard definition of phishing should be applicable in most of phishing concept that are presently defined. Consequently, the high level of abstraction and is required to build common definition on phishing. We also argued that the definition of phishing should not focus on the technology being used but rather on the methodology how the deception being conducted, an “act” if you will. Therefore, We follow the definition of phishing by Lastdrager [36] which stated:

“Phishing is a scalable act of deception whereby impersonation is used to obtain information from a target”

According to Lastdrager [36], to achieve this universal definition, a systematic review of literature up to August 2013 was conducted along with manual peer review, which resulted in 113 distinct definitions to be analyzed. We thereby agree with Lastdrager [36] that this definition addresses all the essential elements of phishing and we will adopt it as universally accepted terminology throughout our research.

2.2 THE COSTS OF PHISHING ATTACKS

It is non-trivial task to find a real cost from phishing attacks in term of money or direct cost. This due to financial damage for bank is only known by banks and most institutions do not share this information with the public. Evidently, Jakobsson et al. argue that phishing economy is consistent with black market economy and does not advertise its successes [28]. On this section, a brief explanation of direct and indirect cost on phishing attack will be illustrated based on literature reviews.

According to Jakobsson et al., direct cost is depicted by the value of money or goods that are directly stolen through phishing attack [28]. While indirect cost is the costs that do not represent the money nor goods that are actually stolen, but it is the costs has to be paid by the people who handle these attacks [28] (i.e. time, money and resources spent to reset people password).

As we mentioned earlier, the difficulty of assessing the damage on phishing attacks is caused by banks and institutions that keep this information themselves and the unwillingness of many users to share to acknowledge that they have been victimized by phishing attacks. This happens because of fear of humiliation, financial loses, or legal liability [28]. Evidently, studies estimate the damage ranging from \$61 million [24] to \$3 billion per year [46] of direct losses to victims in the US only [25][51]. In addition, the Gartner Group claimed to estimate of \$1.2 billion direct losses of phishing attack to US banks and credit card companies for the year 2004 [38]. By the 2007, it escalated to more than \$3 billion loss [47]. The estimation also performed by TRUSTe and Ponemon Institute that stated the cost of phishing attack was up to \$500 millions losses in the US for the same year ¹. Recently, RSA FraudAction gives monthly reports of how much the global phishing cost and we compiled them together to make a line graph in Figure 1 [20]. However, they do not specify whether this damage is direct cost or indirect cost. In their study, we can see that there are fluctuation of losses in term of money. Furthermore, this total cost is indeed in accordance with the total cost ranging from \$61 million to \$3billion per year [24, 46, 25, 51].

Figure 1: Global phishing cost from January 2014 until June 2014 [20]

2.3 MODUS OPERANDI

As we mentioned earlier, Phishing attack is a form of cybercrime. The technique of the attack usually carried out firstly by creating a fake website that spoofs legitimate website such as financial website, either identical or not identical as long as the phishers get responds from unsuspected victims. After that, the phishers will try to trick the potential victim to submit important information such as usernames, passwords, PINs, etc. through a fake website that they have created or through email reply from victims. With the information obtained, they will try to steal money from their victims if target institution is a bank. Phishers employ variety of techniques to trick potential victims to access their fraudulent website. One of the typical ways is by sending illicit email in a large scale claiming to be from legitimate institution. In the email content, they usually imitate an official-looking logo, using good business language style and often also forge the email headers to make it look like originating from legitimate institution. For example, the content of the email is to inform the user that the bank is changing its IT infrastructure, and request urgently that the customer should update their data with the consequence of losing their money if the action does not take place. When the user click the link that was on the email message, they will be redirected to a fraudulent website, which will prompt the victim to fill in the details of their information. While there are various techniques of phishing attack, we will address the common phases of phishing that we ana-

lyzed by literature survey by several studies and also we will address our own phishing phases. These phases are compiled in [Table 1](#).

Table 1: Compilation of phishing phases

J. Hong [25]
<ol style="list-style-type: none"> 1. Potential victims receive a phish 2. The victim may take a suggested action in the message 3. The phisher monetizes the stolen information
Frauenstein, et al. [21]
<ol style="list-style-type: none"> 1. Planning 2. Email Design 3. Fabricated story 4. Threatening tone/Consequences 5. Spoofed website
Wetzel [69]
<ol style="list-style-type: none"> 1. Planning 2. Setup 3. Attack 4. Collection 5. Fraud 6. Post-attack
Tally, et al. [65]
<ol style="list-style-type: none"> 1. The attacker obtains E-mail addresses for the intended victims 2. The attacker generates an E-mail that appears legitimate 3. The attacker sends the E-mail to the intended victims in a way that appears legitimate and obscures the true source 4. The recipient opens a malicious attachment, completes a form, or visits a web site 5. Harvest and exploitation
Emigh [18]

1. A malicious payload arrives through some propagation vector
2. The user takes an action that makes him or her vulnerable to an information compromise
3. The user is prompted for confidential information, either by a remote web site or locally by a Web Trojan
4. The user compromises confidential information
5. The confidential information is transmitted from a phishing server to the phisher
6. The confidential information is used to impersonate the user
7. The phisher engages in fraud using the compromised information

Nero et al. [52]

1. Preparation
2. Delivery of the Lure
3. Taking the Bait
4. Request for Confidential Information
5. Submission of Information
6. Collection of Data
7. Impersonation
8. Financial Gain

Based on the example scenario explained earlier, phishing attacks may consist of several phases. J. Hong [25] argued that there are three major phases. while Frauenstein, et al. [21] suggested that there are five main processes are used to perform phishing attacks based on the perspective of the attacker.

As we illustrated in Figure 2, on the first process is called *Planning*, a phisher usually would do some reconnaissance on how would the attack is executed and what information would be obtained from the victim. On the second process, the phisher would think about the design of the email. This email is desired by the phisher to look as legit as possible to potential victim. For this purpose, target institutions logo, trademark, symbol, etc. are used to make the content look official to the victim. The author called this process as *Email Design*. Figure 3 illustrates the example of fake ING bank logo in a phishing email to create “legitimate” feel². On the third process, the phisher

² <http://www.martijn-onderwater.nl/wp-content/uploads/2010/03/ing-phishing.jpg>

Figure 2: Phishing processes based on Frauenstein[21]

fabricates a story to make potential victim think that email is important. To achieve users attention, phisher might build up a story about system upgrade, account hijacked or security enhancement so that the victim would feel obliged to be informed. Evidently, this technique corresponds with Cialdini [6] that suggests there are six principles to persuade people to comply with a request. On the fourth process, a phisher usually include *threatening tone* or explain the urgency and consequences if the potential victim chooses not to take action desired by the phisher (for example; account removal, account blocked, etc.). Consequently, users may fear of their account being deleted. The last process involved with fraudulent website that has been created by the phisher. Users may falsely believe to the message given in the email and may click a Uniform Resource Locator (URL) that is embedded in the email. Subsequently, the URL would redirect users to a *spoofed website* which may prompt users' sensitive information. Furthermore, the website might be created to be as similar as possible to the target institution's website, so that potential victim may still believe that it is authentic. We will explain more on Cialdini's six basic tendencies of human behavior in generating positive response to persuasion [6] in a later section.

Considering that phishing attack is a process, Wetzel [69] suggested a taxonomy to make sense of the complex nature of the problem by mapping out a common attacks lifecycle, and a possible set of activities attackers engage in within each phase. The taxonomy is illustrated in Figure 4. We speculated that Wetzel's taxonomy is not analogous with Frauenstein's main phishing processes [21]. The difference is that Frauenstein et al. only focus in the design of the attack while Wetzel has added several phases like *Collection*, *Fraud* and *Post-attack*, therefore, Wetzel taxonomy is more holistic in term of phishing.

As we listed Wetzel's taxonomy in Table 1, we explain more of the taxonomy as follows:

Figure 3: Example of fake ING logo in phishing email

Figure 4: Phishing attack taxonomy and lifecycle[69]

1. *Planning*: Preparation carried out by the phisher before continue to the next phase. Example activities include identifying targets and victims, determine the method of the attack, etc.
2. *Setup*: After the target, victim and the method are known, the phisher would craft a platform where the victim's information could be transmitted and stored, for example: fraudulent web-site/email.
3. *Attack*: Phisher distributes their fraudulent platform so that it can be delivered to the potential victims with fabricated stories.
4. *Collection*: Phisher collects valuable information via response from the victims
5. *Fraud*: Phiser abuses victim's information by impersonates the identity of the victim to the target. For example, A has gained B's personal information to access C so that A can pose as B to access C.
6. *Post-attack*: After the phisher gained profit from the attack and abuse phases, a phisher would not want to be noticed or detected by authority. Thus, phisher might need to destroy evidence of the activities that he/she previously were executed.

Tally, et al. suggest that there are several phases involved in phishing attack based on the attacker's point of view [65]:

"1. The attacker obtains E-mail addresses for the intended victims. These could be guessed or obtained from a variety of sources" this fits with planning phase.

"2. The attacker generates an E-mail that appears legitimate and requests the recipient to perform some action" - fits with design phase.

"3. The attacker sends the E-mail to the intended victims in a way that appears legitimate and obscures the true source" - fits with delivery and attack phase.

"4. Depending on the content of the E-mail, the recipient opens a malicious attachment, completes a form, or visits a web site" - fits with attack phase.

"5. The attacker harvests the victim's sensitive information and may exploit it in the future" - fits with fraud phase.

Additionally, the phases described by Tally, et al. [65] are comparable with the information flow explained by Emigh[18] represented in Figure 5.

Emigh [18] suggests the information flow of phishing attacks has seven phases. These phases is explained as follow:

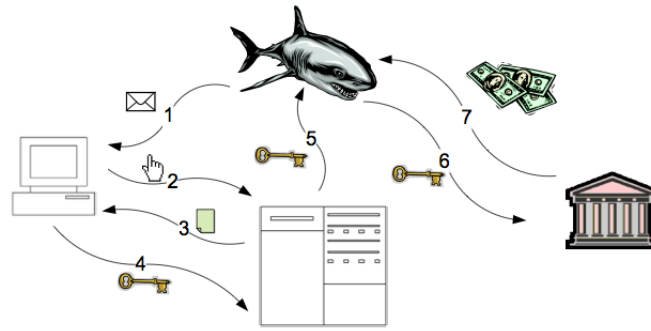

Figure 5: Flow of information in phishing attack [18]

- “1. A malicious payload arrives through some propagation vector.
2. The user takes an action that makes him or her vulnerable to an information compromise.
3. The user is prompted for confidential information, either by a remote web site or locally by a Web Trojan.
4. The user compromises confidential information.
5. The confidential information is transmitted from a phishing server to the phisher.
6. The confidential information is used to impersonate the user.
7. The phisher engages in fraud using the compromised information.” [18]

Phishing attack steps performed by the phisher are also addressed by Nero, et al [52]. In their study, a successful phishing attack involves several phases:

- “1. Preparation
2. Delivery of the Lure
3. Taking the Bait
4. Request for Confidential Information
5. Submission of Information
6. Collection of Data
7. Impersonation
8. Financial Gain” [52]

Based on our analysis by looking at other phases from various sources, there is a major similarity between them. Therefore, we would like to define and design our own phase that are integrated with three key components suggested by Jakobsson, et al. [28]. These key components are include *the lure*, *the hook* and *the catch*. As we designed

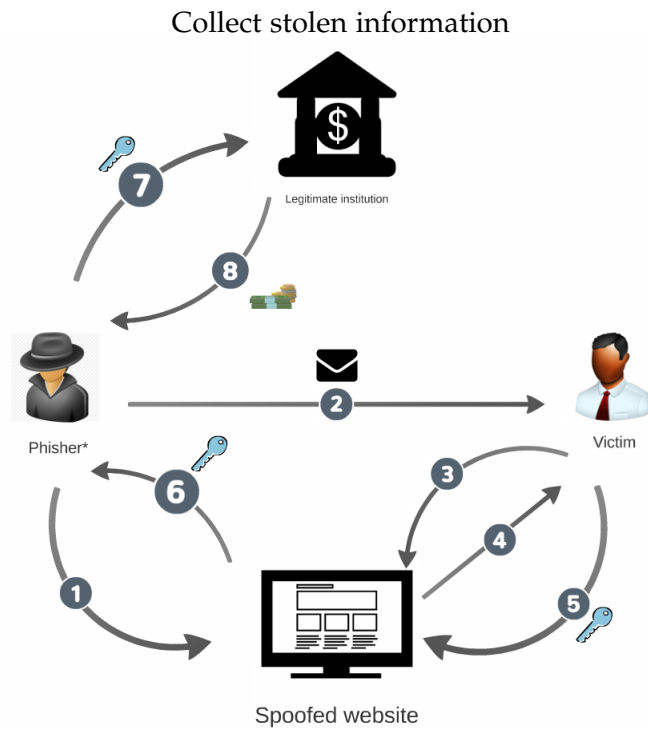

Figure 6: Information flow phishing attack

in Figure 6, we synthesized these three components with our phases based on the attacked point of view as follows:

- The lure
 1. Phishers prepare the attack
 2. Deliver initial payload to potential victim
 3. Victim taking the bait
- The hook
 4. Prompt for confidential information
 5. Disclosed confidential information
 6. Collect stolen information
- The catch
 7. Impersonates victim
 8. Received pay out from the bank

It is important to know that on phase 3 which says victim taking the bait, it might be directed to spoofed website, comply to reply the email, comply to open an attachment(s) or comply to call by phone. However, in Figure 6, we only illustrate the phases if the bait was using spoofed website.

2.4 TYPES OF PHISHING

In January 2014, 8300 patients data are being compromised in medical company in the US [22]. The data includes names, addresses, date of birth and phone numbers were being stolen. Other than demographic information, clinical information associated with this data was also stolen, including social security numbers. In the April 2014, phishers have successfully stolen US\$163,000 from US public school based on Michigan [2]. It has been said that the email prompted to transfer money is coming from the finance director of the school. In March 2014, Symantec has discovered phishing attack aimed at Google drive users [61]. The attack was carried firstly with incoming email asking for opening document hosted at Google docs. Users that have clicked on the link are taken to fraudulent Google login page prompted Google users credentials. Interestingly, the URL seems very convincing because it hosted on Google secure servers. We hypothesized that even more phishing incidents on financial area as well, but sometimes the news is kept hidden due to creditability reason.

One may ask, what type of phishing are these? What type of phishing commonly used nowadays? Evidently, based on the cost of phishing attacks in Section 2.2, the threat of phishing attacks is still alarming and might be evolving in the future with more sophisticated technique of attacks. For this reason, it might be useful to provide a brief insight on popular variants of phishing that currently exist. We will briefly explain the types of phishing which are the most relevant to our research based on Jakobsson, et al. [28]. These types of phishing is strongly related to the phishing definition that we used, because all phishing based act of deception by the phishers.

2.4.1 *Deceptive phishing*

There are many variations based on deceptive phishing schemes. Typical scenario of deceptive phishing schemes is to send a large amount of illicit emails containing call to action asking recipients to click embedded links [28]. These variations include cousin domain attack. For example, legitimate PayPal website addressed as `www.paypal.com`, this cousin domain attacks confuse potential victims to believe that `www.paypal-security.com` is a subdivision of the legitimate website due to identical looking addresses. Similarly, homograph attacks create a confusion using similar characters to its addresses. For example, `www.paypal.com` and `www.paypa1.com`, both addresses look the same but on the second link, it uses “1” instead of “l”.

Moreover, phishers may embed a login page directly to the email content. This suggests the elimination of the need of end-users to click on a link and phishers do not have to manage an active fraud-

ulent website. IP addresses are often used instead of human readable hostname to redirect potential victim to phishing website and JavaScript is used to take over address bar of a browser to make potential victims believe that they are communicating with the legitimate institution. We will also see few examples of malicious JavaScript on our preliminary analysis section.

Another type of deceptive phishing scheme is rock-phish attacks. They held responsible for half a number of reported incidents worldwide in 2005 [48]. These attacks evade email filters by utilizes random text and GIF images which contain the actual message. Rock phish attacks also utilize a toolkit that capable to manage several fraudulent websites in a single domain. Sometimes, deceptive phishing schemes lead to installation of malware when users visit fraudulent website and we will describe malware based phishing scheme in the next section.

2.4.2 *Malware-based phishing*

Generally, malware based phishing refers to any type of phishing which involves installing malicious piece of software onto users' personal computer [28]. Subsequently, this malware is used to gather confidential information from victims instead of spoofing legitimate websites. This type of phishing incorporates malwares such as keyloggers/screenloggers, web Trojans and hosts file poisoning.

2.5 BAD NEIGHBORHOODS ON PHISHING

In the physical world, there are parts of certain area that have higher crime rates than others (eg. Bronx in the US) which called hotspots. Evidently, it is statistically more likely that a crime will occur compared to other locations [50]. To better illustrate this analogy, the police department in Belgium [11] has put up statistical information regarding crime rates in the country. Figure 7 shows an example in 2013; there were up to 5525 car theft incidents recorded and we can see there are certain areas that have higher probability that a car got stolen. For example, Antwerp had 415 incidents whereas Berlare had only 1 car theft incident [10]. The data is not necessarily based on cities, it can be based on the residential area within a city. This holds true that much higher crime rates in a concentrated location compared to any other locations. It is called bad neighborhood.

To reduce the crime rates in a bad neighborhood, it makes sense that the authority should put more enforcement in this location. Moreover, the citizen should avoid this location as much as they can if they want to feel much safer. Evidently, Moura, et al. suggest that the existence of bad neighborhood phenomenon also occurs in the Internet world called "Internet bad neighborhoods" [50]. There are certain net-

Figure 7: Belgium police record on car theft incidents in 2013

works of Internet infrastructure that contain more malicious activities than other networks. For our preliminary analysis, we will adopt the formal definition of Internet bad neighborhoods or Internet Badhoods by [50] which states:

“Internet bad neighborhood is a set of IP addresses clustered according to an aggregation criterion in which a number of IP addresses perform a certain malicious activity over a specified period of time”

Several studies have suggested that the source of the Internet Badhoods tend to be concentrated in certain portions of Internet Protocol (IP) address space [60, 8, 3]. Moura, et al. suggest that Internet Badhoods do not always only based on network prefixes level (e.g. /24, /32, etc..) but it can be aggregated into several levels (ISPs, Countries) [50]. Moreover, Internet Badhoods may vary depending on which application exploited. While spam is most likely distributed all around the world, however, phishing Badhoods are most likely concentrated in developed countries (e.g. US) [50]. This suggests that phishing sites are required to have more reliable hosts in terms of availability, while spams are not. We will see in Chapter 3 that consists of our preliminary analysis on phishing Badhoods.

2.6 CURRENT COUNTERMEASURES OF PHISHING ATTACKS

There are various types of phishing countermeasures that implemented in different levels. Purkait has conducted an extensive research in reviewing these countermeasures which are available up until 2012 and their effectiveness [59]. He suggests that there is a classification of phishing countermeasures in separate groups and according to Purkait [59], these groups are listed as follows:

- Stop phishing at the email level
- Security and password management toolbars
- Restriction list

- Visually differentiate the phishing site
- Two factor and multi channel authentication
- Takedown, transaction anomaly detection, log files
- Anti phishing training
- Legal solution

In addition, Parmar, et al. suggests that phishing detection can be classified into two types; user training approach and software classification approach [55]. He illustrated a diagram and a table that summarizes phishing detection as countermeasures in a broad view [55]. They also argued the advantages and disadvantages of each category [55]. However, as our research mainly focuses in synthesizing phishing email with cialdini's six principles of persuasion [6], we will only briefly discuss phishing countermeasures at *restriction list* group (i.e. Phishtank), *email level* (i.e. machine learning) and *anti phishing training* group (i.e PhishGuru).

2.6.1 Phishing detection

2.6.1.1 Phishtank

One of the common approaches to detect phishing attacks is the implementation of restriction list. As the name suggest, it prevents users to visit fraudulent websites. One of the efforts to achieve restriction list, is to derive phishing URLs from Phishtank. Phishtank is a black-listing company specifically for phishing URLs and it is a free community web based where users can report, verify and track phishing URLs [54]. Phishtank stores phishing URLs in its database and is widely available for use by other companies for creating restriction list. Some of the big companies that are using Phishtank's data includes; Yahoo Mail, McAfee, APWG, Web Of Trust, Kaspersky, Opera and Avira. In this section, we will discuss how the current literatures have to do with phish data provided by Phishtank. The first step to achieve the list of relevant literatures regarding phishtank is by keyword search in Scopus online library. By putting "Phishtank" as a keyword search, it results in 12 literatures. The next step, we read the all the abstracts and conclusions of the resulting keyword search and we decided 11 literatures that are relevant to our research. Lastly, Table 2 summarizes the papers selected and its relevancy with Phishtank

Table 2: Summary phishtank studies

Paper title	First author	Country	Relevancy with phishtank
-------------	--------------	---------	--------------------------

Evaluating the wisdom of crowds in assessing phishing website [49]	Tyler Moore	United Kingdom	Examine the structure and outcomes of user participation in Phishtank. The authors find that Phishtank is dominated by the most active users, and that participation follows a power law distribution and this makes it particularly susceptible to manipulation.
Re-evaluating the wisdom of crowds in assessing web Security [5]	Pern Hui Chia	Norway	Examine the wisdom of crowds on web of trust that has similarity with Phishtank as a user based system.
Automatic detection of phishing target from phishing webpage [39]	Gang Liu	China	Phishtank database is used to test the phishing target identification accuracy of their method.
A method for the automated detection of phishing websites through both site characteristics and image analysis [70]	Joshua S. White	New york, US.	Phishtank database is used to perform additional validation of their method. They also collect data from twitter using twitter's API to find malicious tweets containing phishing URLs
Intelligent phishing detection and protection scheme for online transaction [1]	P.A. Barraclough	Newcastle, United Kingdom	Phishtank features is used as one of the input of neuro fuzzy technique to detect phishing website. The study suggested 72 features from Phishtank by exploring journal papers and 200 phishing website.
Towards preventing QR code based attacks on android phone using security warning [73]	Huiping Yao	New Mexico, US.	Phishtank API is used for lookup whether the given QR containing phishing URL in the Phishtank database.
A SVM based technique to detect phishing URLs [26]	Huajun Huang	China	Phishtank database is used as validation resulting 99% accuracy by SVM method, plus the top ten brand names in Phishtank archive is used as features in SVM method.
Socio technological phishing prevention [23]	Gaurav Gupta	Australia	Analyze the Phishtank verifiers (individual/organization) to be used as anti phishing model.

An evaluation of lightweight classification methods for identifying malicious URLs [17]	Shaun Egan	Grahamstown, South Africa	Indicating that lightweight classification methods achieves an accuracy of 93% to 96% when trained data from Phishtank.
Phi.sh/\$oCiaL: The phishing landscape through short URLs [4]	Sidharth Chhabra	Delhi, India	Phishtank database is used to analyze suspected phish that is done through short URLs.
Discovering phishing target based on semantic link network [68]	Liu Wenyin	Hong Kong	Phishtank database is used as test dataset to verify their proposed method (Semantic Link Network)

From our literature survey, we know that Phishtank is crowd-sourced platform to manage phishing URLs. For that reason Moore, et al. aims to evaluate the wisdom of crowds platform accomodated by Phishtank [49]. Moore, et al. suggest that the user participation is distributed according to power law. It uses to model data which frequency of an event varies as a power of some attribute of that event [35]. Power law also applies to a system when large is rare and small is common ³. For example, in the case of individual weatlh in a country, 80% of the all wealth is controlled by 20% of population in a country. It makes sense that in Phishtank's verification system, a single highly active user's action can greatly impact the system's overall accuracy. Table 3 summarizes the comparison performed by [49] between Phishtank and closed proprietary anti-phishing feeds⁴. Moreover, there are some ways to disrupt Phishtank verification system; submitting invalid reports accusing legitimate website, voting legitimate website as phish, and voting illegitimate website as not phish. While all the scenarios described are for the phishers' benefit, the last scenario is more direct and the first two actions rather subtle intention to undermine Phishtank credibility.

To put it briefly, the lesson of crowd sourced anti-phishing technology such as Phishtank is that the distribution of user participation matters. It means that if a few high value participants do something wrong, it can greatly impact overall system [49]. Also, there is a high probability that bad users could also extensively participate in submitting or verifying URLs in Phishtank.

2.6.1.2 Machine learning approach

The fundamental of phishing detection system would be to distinguish between phishing websites and the legitimate ones. As we previously discussed, the aim of phishing attack is to gather confidential

³ <http://kottke.org/03/02/weblogs-and-power-laws>

⁴ The author conceals the identity of the closed proprietary company

Phishtank	Proprietary
10924 URLs	13318 URLs
8296 URLs after removing duplication	8730 URLs after removing duplication
Shares 5711 URLs in common 3019 Unique to the company feeds while 2585 only appeared in Phishtank	
586 rock-phish domains	1003 rock phish domains
459 rock phish domains found in Phishtank	544 rock phish domains not found in Phishtank
Saw the submission first	11 minutes later appear on the feed
16 hours later after its submission for verification (voting based)	8 second to verified after it appears
Rock phish appear after 12 hours appeared in the proprietary feed and were not verified for another 12 hours	

Table 3: Comparison summary [49]

information from potential victims. To do this, phishers often prompt for this information through fraudulent websites and masquerade as legitimate institutions. It does not make sense if phishers created them in a way very distinctive with its target. It may raise suspicions with result of unsuccessful attack. To put it another way, while it might be true, we speculated that most of the phishing websites are mostly identical with its legitimate websites as target to reduce suspiciousness from potential victim.

In contrast of one of blacklisting technique we saw in Phishtank that heavily depend on human verification, researchers make use of machine learning based technique to automatically distinguish between phishing and legitimate either websites or email. Basically, machine-learning system is a platform that can learn from previous data and predict future data with its classification, in this case, phishing and legitimate. In order for this machine to learn from data, there should be some kind of inputs to classify the data, it is called features or characteristics.

Furthermore, there are also several learning algorithms to classify the data, such as, logistic regression, random forest, neural networks and support vector machine. However, for the sake of simplicity of our research, we will not discuss about the learning algorithm that is currently implemented. We will only introduce three features that are used in machine learning based detection.

URL	www.naturenilai.com/form2/paypal/webscr.php?cmd=_login	
Auto-Selected	name=www, name=naturenilai, tld=com, dir=form2, dir=paypal file=webscr, ext=php, arg=cmd, arg=login	
Obfuscation-Resistant	URL	len=54, n_dot=3, blacklist=1
	Domain Name	len=19, IP=0, port=0, n_token=3, n_hyphen=0, max_len=11
	Directory	len=14, n_subdir=2, max_len=6, max_dot=0, max_delim=0
	File Name	len=10, n_dot=1, n_delim=0
	Argument	len=11, n_var=1, max_len=6, max_delim=1

Figure 8: Example lexical features [37]

There are vast amount of features to utilize machine learning to detect phishing attack. Literatures are selected by keyword search such as “phishing + detection + machine learning”. We analyze three features: lexical feature, host-based feature and site popularity feature. Each of these features will be introduced briefly as follows.

1. Lexical features

Lexical features (URL based features) are based on the analysis of URL structure without any external information. Ma, et al. suggest that the structure URL of phishing may “look” different to experts [43]. These features include how many dots exist, the length, how deep the path traversal do the URL has or if there any sensitive words present in a URL. For example the URLs <https://www.paypal.com> and <http://www.paypal.com.example.com/> or <http://login.example.com/> or <http://www.paypal.com/>, we can see that the domain paypal.com positioned differently, with the first one being the benign URL. Figure 8 shows an example analysis of lexical features in a phishing URL [37].

Lexical features analysis may have performance advantage and reduces overhead in term of processing and latency, since it only tells the machine to learn URL structure. 90% accuracy is achieved when utilizing lexical features combined with external features such as WHOIS data [37]. Egan, et al. conducted an evaluation of lightweight classification that includes lexical features and host based features in its model [17]. The study found that the classification based on these features resulted in extremely high accuracy and low overhead. Table 4 lists the existing lexical features that are currently implemented by two different studies [72, 40]. However, Xiang, et al.[72] pointed out that URLs structure could be manipulated with little cost, causing the features to fail. For example, attackers could simply remove embedded domain and sensitive words to make their phishing URLs look legitimate. Embedded domain feature examines whether a domain or a hostname is present in the path segment [72], for example, <http://www.example.net/pathto/www.paypal.com>. Suspicious URL feature examine whether the URL has “@” or “-”, the present of “@” is examined in a URL because when the symbol “@” is used, the string to the left will be discarded. Furthermore, according to

Haotian Liu, et al. [40]	Guang Xiang, et al. [72]
<ul style="list-style-type: none"> • Length of hostname Length of entire URL • Number of dots • Top-level domain • Domain token count • Path token count • Average domain token length of all dataset • Average path token length of dataset • Longest domain token length of dataset • Longest path token length of dataset • Brand name presence • IP address presence • Security sensitive word presence 	<ul style="list-style-type: none"> • Embedded domain • IP address presence • Number of dots • Suspicious URL • Number of sensitive words • Out of position top level domain (TLD)

Table 4: Existing lexical features [40, 72]

[72], not many legitimate websites use “-” in their URLs. There are also plenty of legitimate domains presented only with IP address and contains more dots. Nevertheless, lexical analysis would be suitable features to use for first phase analysis in a large data [17].

2. Host based features

Since phishers often hosted phishing websites in less reputable hosting services and registrars, host-based features are needed to observe on the external sources (WHOIS information, domain information, etc.). A study suggests host-based features have the ability to describe where phishing websites are hosted, who owns them and how they are managed [43]. Table 5 shows the host-based features from three studies that are currently used in machine learning phishing detection. These studies are selected only for example comparison.

Each of these features does matter for phishing detection. However, as our main objective is synthesizing cialdini’s principle with phishing emails, we will not describe each of these features in detail. It is noteworthy that some of the features are subset of another feature, for instance, autonomous system number (ASN), IP country and number of registration information are derived from WHOIS information. Nevertheless, we will only explain few of them that we assume the most crucial.

1. WHOIS information: Since phishing websites and hacked domains are often created at relatively young age, this information could provide the registration date, update date and expiration

Justin Ma, et al.[43, 42]	Haotian Liu, et al. [46][40]	Guang Xiang, et al. [72]
<ul style="list-style-type: none">• WHOIS data• IP address information• Connection speed• Domain name properties	<ul style="list-style-type: none">• Autonomous system number• IP country• Number of registration information• Number of resolved IPs• Domain contains valid PTR record• Redirect to new site• All IP's are consistent	<ul style="list-style-type: none">• Age of Domain

Table 5: Host-based features [43, 42, 40, 72]

date. Domain ownership would also be included; therefore, a set of malicious websites with the same individual could be identified.

2. IP address information: Justin Ma, et al. used this information for identify whether or not an IP address is in blacklist [42, 43]. Besides the corresponding IP address, it provides records like nameservers and mail exchange servers. This allows the classifier to be able to flag other IP addresses within the same IP prefix and ASN.
3. Domain name properties: these include time to live (TTL) of DNS associated with a hostname. PTR record (reverse DNS lookup) of a domain could also be derived whether it is valid or not.
4. Site popularity features

Site popularity could be an indicator whether a website is phishy or not. It makes sense if a phishing website has much less traffic or popularity than a legitimate website. According to [72], some of the features indicated in Table 6 are well performed when incorporated with machine learning system.

1. Page in top search results: this feature originally used by [74] to find whether or not a website shows up on the top N search result. If it is not the case, the website could be flagged as phishy since phishing websites have less chance of being crawled [72]. We believe this feature is similar to Number of external links feature since both of them are implying the same technique.

Guang Xiang, et al. [72]	Haotian Liu, et al. [40]
<ul style="list-style-type: none"> • Page in top search results • PageRank • Page in top results when searching copyright company name and domain • Page in top results when searching copyright company name and hostname 	<ul style="list-style-type: none"> • Number of external links • Real traffic rank • Domain in reputable sites list

Table 6: Site popularity features [72, 40]

2. PageRank: this technique is originally introduced by Google to map which websites are popular and which are not, based on the value from 0 to 10. According to [72], the intuitive rationale of this feature is that phishing websites are often have very low PageRank due to their ephemeral nature and very low incoming links that are redirected to them. This feature similar to Real traffic rank feature employed by [40] where such feature can be acquired from alexa.com.
3. Page in top results when searching copyright company name and domain/hostname features are complement features of Page in top search results feature with just different queries. Moreover, we believe they are also similar to Domain in reputable sites list feature since they are determining the reputation of a website. The first two features can be identified by querying google.com [72] and the latter feature can be obtained from amazon.com [40].

2.6.2 Phishing prevention

Phishing attacks aim to by-pass technological countermeasures by manipulating users' trust and can lead to monetary losses. Therefore, human factors take a big part on the phishing taxonomy, especially in the organizational environment. Human factor in phishing taxonomy comprised of education, training and awareness [21]. Figure 9 illustrates where human factor takes part on phishing threats [21]. User's awareness of phishing has been explored by several studies [29, 21, 18, 33, 30, 15] as preventive measure against phishing attack. According to ISO/IEC 27002 [21][9], it has been shown that information security awareness is important and it has been critical

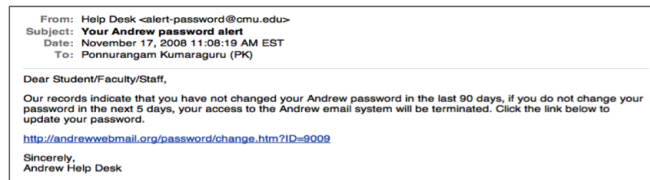

Figure 9: Holistic anti-phishing framework [21]

success factors to mitigate security vulnerabilities that attack user's trust. One approach to hopefully prevent phishing attack was by implementing anti phishing warning/indicator. Dhamija, et al suggest that users often ignore security indicators thus makes them ineffective [12]. Even if users notice the security indicators, they often do not understand what they represent.

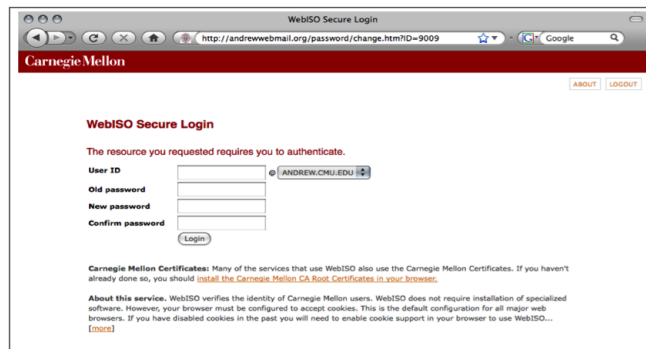

Moreover, the inconsistency of positioning on different browsers makes them much difficult to identify phishing [32]. Evidently, Schechter, et al. pointed out that 53% of their study participants were still attempting to provide their confidential information, even after their task was interrupted by strong security warning [62]. Therefore, these suggest that an effective phishing education must be added as a complementary strategy to complete technical anti-phishing measure as a strong remedy to detect phishing websites or emails.

Phishing education for online users often by instructing not to click links in an email, ensure that SSL is present and to verify that the domain name is correct before giving information, and other similar education. This traditional practice evidently has not always effective [18]. One may ask what makes phishing education effective? A study suggests that in order online users to be aware of phishing threats, is to really engage them to so that they understand how vulnerable they are [44]. To do this, simulated phishing attacks often performed internally in an organization. Figure 10 shows a simulated phishing email and website carried out by Kumaraguru, et al. from PhishGuru [34]. As a result, this scenario puts them in the ultimate teachable moment if they fall for these attacks.

Phishguru is a security training system operated by Wombat security technology that teaches users not to be deceived by phishing attempts by simulation of phishing attacks[63]. They claimed

(a) simulated phishing email [34]

(b) simulated phishing website [34]

(c) simulated phishing message [34]

Figure 10: Simulated phishing attack [34]

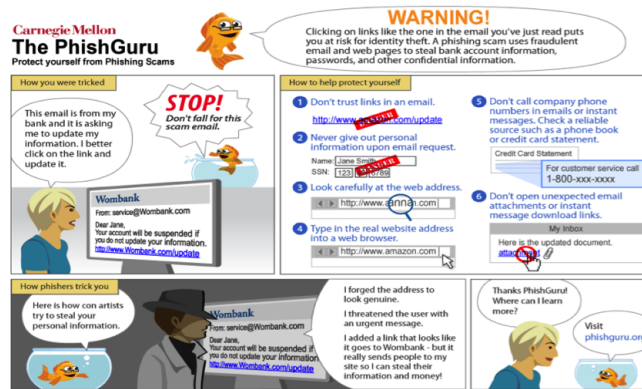

Figure 11: Embedded phishing training [34]

Phishguru provides more effective training than traditional training as it is designed to be more engaging. Figure 11 illustrates how embedded phishing training was presented by PhishGuru.

Kumaraguru, et al. investigates the effectiveness of embedded training methodology in a real world situation [34]. Evidently, they indicated that even after 28 days after training, users trained by PhishGuru were less likely to click the link presented in the simulated phishing email than those who were not trained. They also find that users who trained twice were less likely to give information to simulated fraudulent website than users who were trained once. Moreover, they argue that the training does not decrease the users' willingness to click on the links from legitimate emails; it means that less likely a trained user did a false positive when he or she requested to give information from true legitimate emails [34]. This suggests that user training strategy as an effective phishing education in order to improve phishing awareness especially in organizational environment.

PRELIMINARY ANALYSIS

Before we go into our main analysis on phishing email dataset, we would like to conduct preliminary analyses on phishtank and phishload datasets. Basic investigation on both datasets were conducted prior

3.1 PHISHING BAD NEIGHBORHOOD IN PHISHTANK

3.1.1 *Preliminary methods*

To examine whether phishing bad neighbors exist in phishing context, we established what tools we could use for our analysis. These tools include:

- www.yougetsignal.com
- www.majesticseo.com/research/neighbourhood-checker.php
- <http://www.ip-address.org/reverse-lookup/reverse-ip.php>
- <http://www.my-ip-neighbors.com/>
- ip-lookup.net
- Mac OS X network utility

We used these tools because they are freely available and capable of doing reverse IP lookup to find bad neighborhood in a particular IP address. We determined that the results given by these tools were sufficient for our basic analysis. We selected 10 valid and online phish URLs from phishtank in sequence on the date of 17 March 2014 and add 21 URLs more in sequence which were valid and online on the date of 24 March 2014.

After preparing 10 valid phishing URL we identified its Top Level Domain (TLD) and Top level IP address. The next step, we evaluated from which country are they from and counted how many characters it has. Next, we identified how many domains are hosted within a neighbors using reverse IP lookup. Lastly, we selected 10 random domains within its domain to be examined whether they are harmful or legitimate.

3.1.2 *Preliminary results*

To fit the table onto the page and avoid a very huge and long table, we put the phishing URLs separately in [Table 8](#) the appendix section.

Table 7: Phishtank URL analysis

URL ID	TLD	TL-IP	No. Do-main found	Random 10 neighbors	Country	URL Length
1	munduslc.com	184.154.233.9	384	3 could not be resolved, 7 legitimate	Chicago, US	163
2	daff-inc.com	203.190.54.3	196	2 could not resolve, 8 legitimate	Jakarta, Indonesia	162
3	cntsiam.com	27.254.67.185	25	1 malware warning, 9 legitimate websites	Bangkok, Thailand	17
4	hockeyfollonica.com	194.184.71.7	297	9 404 error, 1 could not be resolved	Italy	165
5	douban.co.uk	193.61.190.231	18	4 legitimate, 1 phishing warning (douban.co.uk itself), 5 errors	UK	123
6	appsgeo.org	195.154.168.222	52	2 reported as phishing (including appsgeo.org), 1 reported untrustworthy (from WOT plugin), 6 legitimate, 1 error	France	164
7	fatihdabak.com	31.169.91.37	97	7 legitimate, 1 hacked, 1 phishing (WOT), 1 error	Turkey	176
8	edirnewebtasarimi.com	95.173.184.22	95	2 hacked, 2 error, 6 legitimate	Turkey	89
9	clientel-pl.com	209.17.116.6	362	10 legitimate	US	115
10	totalwhiteboard.com.au	203.84.238.17	224	10 legitimate	Australia	161
11	altervista.org	216.127.94.127	222	2 redirect to en.altervista.org (free host provider), 6 legitimate, 2 could not be resolved	US	66
12	mytrickworld.com	192.254.71.149	102	1 could not be resolved, 2 empty pages, 7 legitimate	US	244
13	toughbook.cl	190.153.181.184	14	7 legitimate, 1 error, 2 request time out	Chile	162

14	doctorsantis.cl	200.63.97.50	426	2 could not be resolved, 2 404 error, 1 hacked, 5 legitimate	Chile	154
15	ankarabayanmodel.com	37.247.101.252	19	1 could not be resolved, 1 Suspended account, 1 expired domain, 6 legitimate, 1 poor reputation (WOT)	Turkey	105
16	theripe.tv	108.162.199.188	378	1 could not be resolved, 1 Under maintenance (warez), 8 Legitimate	US	185
17	yoursyours.com	204.77.0.196	18	1 warning (yoursyours.com, 1 could not be resolved, 8 legitimate	US	127
18	vidavallarta.com.mx	69.162.95.178	137	7 legitimate, 1 error (bandwidth limit exceeded), 2 could not be resolved	US	207
19	alvaroestrella.com	67.222.145.50	422	3 could not be resolved, 7 legitimate	US	117
20	no domain name	178.210.162.252	25	10 legitimate	Turkey	67
21	31obxgg.com	103.27.127.142	No known domains hosted on this IP	hacked domain http://31obxgg.com/	Hong Kong	108
22	affordablebestwebsitehosting.com	173.214.178.24	25	4 suspected phishing (WOT warning), 1 suspended account, 1 could not be resolved, 4 legitimate	US	150
23	alwaysplotting.com	208.97.149.71	25	9 legitimate, 1 error (403 forbidden)	US	138

24	kcn.ru	193.232.252.56	No known domains hosted on this IP	No known domains hosted on this IP	Russia	124
25	cleanwheel.net	173.243.123.58	9	3 could not be resolved, 2 domain expired, 1 timeout, 1 error establishing a database connection, 2 legitimate	US	58
26	avatur.net	62.99.79.26	25	1 legitimate, 2 phishing warning, 6 access denied, 1 could not be resolved	Spain	146
27	vicfer.mx	198.27.68.106	No known domains hosted on this IP. However, noticed that the last 5 URLs are from the same IP (198.27.68.106) So that it makes them neighbours		Canada	80
28	latitud-x.com.mx	198.27.68.106			Canada	104
29	carycar.com.mx	198.27.68.106			Canada	85
30	gentilee.com.ar	198.27.68.106			Canada	82
31	uniredmx.com	198.27.68.106			Canada	83

Based on our analysis we know that we have 31 phish URLs. 3 of them are hacked domain (10%) while 11 domains (35%) have the possibilities of harmful instances. It makes 17 domains (55%) do not have the possibilities of bad neighborhoods. In conclusion, while there are some possibilities of bad neighborhood, there are much more legitimate domains attributed from a phishing domain as well.

3.2 FINDING DIFFERENCES OF PHISHING VS ORIGINAL IN PHISHLOAD DATABASE

3.2.1 Preliminary methods

To find differences between phishing webpage and its legitimate one, we utilized the differences of their HTML source codes. However, Phishtank does not have HTML source code of their phishing webpage, therefore, we decided to shift our analysis to Phishload database [45] which is collected from Phishtank as well. The phishload test database is a set of visited phishing websites and original websites that have been visited and scanned for testing purposes. Over a period of several weeks current phishing links from Phishtank have been collected and then been visited by a controlled instance of Firefox browsers. Derived from readme.txt files of phishload database, it has been created on 22 March 2013. It has 11215 URLs with 1185 non phishing URLs and 3718 assigned phishing pages [45]. Moreover, the tables of the database is already explained by Maurer on his website [45].

The methods to carry out this preliminary analysis are as follows:

1. Select all parent = NULL and site = paypal
 - SQL command: `SELECT * FROM 'websites' WHERE 'name' = 'paypal';` does not result in anything/resulting in zero rows
 - `SELECT * FROM 'websites' WHERE 'parent' IS NULL AND 'urlBasedomain' = 'paypal.com';` result = 1 row
2. Save the ID and the field of HTML content
 - ID = 34 and HTML content are saved => paypal original.html
3. Find 20 phish websites where parent = ID
 - `SELECT * FROM 'websites' WHERE 'parent' = 34;` Resulting in 1315 rows
 - `SELECT * FROM 'websites' WHERE 'parent' = 34 LIMIT 20;` Resulting in 20 rows Export to SQL file => 20 phish paypal.sql
4. Compare legitimate paypal and the 20 fake paypal websites

All of the 20 examinations were done manually by finding the differences between the original web page against individual phishing web page stored in Phishload database.

3.2.2 Preliminary results

Through the HTML source code analysis, we may find malicious irregularities that ask victims to input their financial information or login credentials. Ludl et al. have defined page properties to characterize a web page before it can be analyzed for indication that might reveal it as a phishing site [41], of course in this experiment, all of the web pages are indicated as phishes according to Phishload. These properties are described as follows:

- Forms: Phishing website aims to trick users to input their sensitive information. Consequently, fake website needs some kind of forms as interface to contain those information. Web Forms may provide a good indicator to distinguish phishing and original.
- Input fields: Original web pages may have web forms with its input fields for users to input necessary information. Similarly, phishing web pages may have the same input fields as the original web page. However, the difference lies in where these information go to.
- Links: General properties of a web page is in its link structure. link(s) structure portrayed by not only links to other webpages, but also the link(s) which embedded in an image within a page. Ludl et al. argued that many phishing web pages contain links to the site they spoof, and evidently, often contain original elements from the web page they targeted [41].
- Script tags: Another good indicator to distinguish a phishing web page is to find out whether it has rouge JavaScript or not. There is a possibility that JavaScript may be used to by-passing Anti-phish so that it will not be detected as a phish [31, 41].

To illustrate, HTML source of the phish website row 1 was gathered and evaluated. It is clear that it is a phish website because inside the HTML source it has function called zzzz() that contains variables that manage the input of victim personal information.

```
function zzzz() {
var tes=true;
var first=document.fox.first_name.value;
var lasto=document.fox.last_name.value;
var doxa=document.fox.dob_a.value;
var doxb=document.fox.dob_b.value;
var doxc=document.fox.dob_c.value;
var numbex=document.fox.cc_number.value;
var email=document.fox.email.value;
var address=document.fox.address1.value;
var zipos=document.fox.zip.value;
var villss=document.fox.city.value;
var phonos=document.fox.phone.value;
var fvv=document.fox.cvv2_number.value;
}
```

We also found an explicit hack comment on the phish row 2:

```
<script type="text/javascript"> // This is an ugly hack until there
is a reliable ondomready function if(typeof PAYPAL != 'unde-
fined'){PAYPAL.core.Navigation.init(); }</script>
```

For the sake of simplicity, we put a detailed of differences table of 20 phishing webpage vs original webpage in the [Section A.1 Table 9](#). Based on our manual analysis, we found out that most of the HTML sources are tampered while maintaining the looks of legitimacy. The alterations consist of irregular scripts, irregular links, suspicious forms and inputs. Only two HTML sources that are completely different from the original source. 4 HTML sources are NULL so overall analysis will be $N = 16$. In conclusion, 87.5% of HTML sources are tampered while maintaining the appearance of original target and 12.5% are completely different from the original. The details of modification can be seen in [Table 9](#).

RESEARCH QUESTION

We begin our research question by presenting frequency table that characterizes the properties of phishing emails in our dataset.

RQ1: What are the characteristics of the reported phishing emails?

1. What are the most targeted sectors?
2. What are the reasons frequently used?
3. What are the methods used?
 - a) How many emails that contain and do not contain hyperlink?
 - b) How many emails that contain hyperlink AND/OR obfuscated link?
 - c) How many emails that contain and do not contain attachment (PDF attachment OR ZIP attachment OR HTML attachment OR Unknown attachment)?
 - d) How many emails that contain hyperlink AND/OR attachment?
 - e) How many emails that contain hyperlink AND NOT request to click link?
 - f) How many emails that contain attachment AND NOT request to open attachment?
 - g) How many emails that request to click link OR request to open attachment OR request email reply OR request to call by phone?
 - h) How many emails that request to click link also request to open attachment?
 - i) How many emails that request to click link AND request to open attachment AND request to email reply AND request to call by phone?

In our coding of cialdini's principles and phishing email dataset, we identified phishing emails with fake logos and signatures that may mistakenly regard them as legitimate by average internet users. For example in the context of phishing email, signature such as "Copyright 2013 PayPal, Inc. All rights reserved" or "Administrator Team" and Amazon logo were used to show the "aura of legitimacy". In

the real world society, telemarketers and seller has been using authoritative element to increase the chance of potential consumer's compliance [66]. It means that they have to provide information in a confident way. Consumers will have their doubt if sellers unsure and nervous when they offer their product and services to consumers. This principle has been one of the strategies in a social engineering attack to acquire action and response from a target [53]. Based on this conception, phishers may also have applied the same principle and as a dominance principle of all other principles. This leads to our second research question below. Therefore, hypotheses are established accordingly to answer **RQ1 (H1, H2, H6, H11)**.

RQ2: How dominance authoritative principle in the dataset?

It is makes sense if government has the authority to compose laws and regulations and to control its citizens. Government sector includes court and police department also authorize to execute penalties if any wrongdoing happens within their jurisdiction. However, government may not have to be likeable to enforce their rules and regulation. Similarly, an administrator who control his network environment may behave in a similar fashion as government. Hence, in our dataset we hypothesize that

H1: There will be a significant association between Government sector and authority principle

H2: Phishing emails which targeting Administrator will likely to have authority principle

Similar to authority principle that may trigger reactance, scarce items and shortage may produce immediate compliance from people. In essence, people will react when their freedom is restricted about valuable matter when they think they are capable to make a choice among different options [57]. For example in phishing email context, an email from Royal Bank inform us that we have not been logged into our online banking account for a quite some time, as a security measure, they must suspend our online account and if we would like to continue to use the online banking facility, we have been asked to click the link provided. Potential victim may perceives their online banking account as their valuable matter to access facility and information about their savings. Consequently, potential vicim may react to the request because of their account could be scarce and restricted. In the real world example, a hard worker bank customer who perceives money is a scarce item may immediately react when his bank inform him that he is in danger of losing his savings due to "security breach". We therefore hypothesize that

H3: There will be a significant correlation between Financial sector and scarcity principle

As we describe in our decision making consideration section, people tend to trust those they like. In a context of persuasion, perpetrators may find it more difficult to portray physical attractiveness, instead they are relying on emails, websites and phone calling [16]. To exhibit charm or charisma to the potential victims, perpetrators may gain their trust by establishing friendly emails, affectionate websites and soothing voice over the phone. In the phishing email context, Amazon praises our existence in an appealing fashion and extremely values our account security so that no one can break it. Based on this scenario, E-commerce/Retails sector may applied likeability principles to gain potential customers. We therefore hypothesize that

H4: Phishing emails which targeting E-Commerce/Retails will likely to have a significant association with likeability principle

Tajfel, et al. argued that people often form their own perception based on their relationship with others in a certain social circles [64]. This lead to affection of something when significant others have something to do with it. Social proof is one of the social engineering attacks based on the behavioral modeling and conformance [71] For example, we tend to comply to a request when a social networking site asks us to visit a website or recommends something and mention that others have been visiting the website as well. Thus, we hypothesize that

H5: Phishing emails which targeting Social networks will likely to have signification association with social proof principle

As we describe in our decision making consideration section, authority has something to do with “aura of legitimacy”. This principle may lead to suggest the limitation on something that we deemed valuable. For example, a perpetrator masquerades as an authority and dressed as police officer halted us on the road, the perpetrator may tell us that we did something wrong and he will held our driving license if we do not pay him the fine. In the phishing email context, an email masquerades as “System Administrator” may tell us that we exceeded our mailbox quota, so the administrator must freeze our email account and we could re-activate it by clicking the link provided in the email. Based on this scenario, we know that it has authority principle and also has scarcity principle. Therefore, we hypothesize that

H6: There will be a significant relationship between authority principle and scarcity principle

We often stumbled a group of people requesting to donate some of our money to the unfortunate people. Evidently, they would use physical attractiveness and kind words to get our commitment to support those people. Once they have got our commitment, they start asking for donation and we tend to grant their request and give some of our money to show that we are committed. Phishing email could be similar, for example, Paypal appreciates our membership on their system and PayPal kindly notifies us that in the membership term of agreement, they would performing annual membership confirmation from its customers. Based on this scenario, we know that the email has likeability principle and also has consistency principle. We would like to know if it is the case with phishing email in our dataset. Therefore, we hypothesize that

H7: Phishing emails that have likeability principle will likely to have consistency principle

We think it make sense if a fraudster tries to make his fake product as genuine as possible and hide the fabricated element of his product. There are also fraudster that did not make his product as identical as the legitimate product. In the phishing email context, we perceives fake product as hyperlink in the email, phishers do not necessarily obfuscates the real URL with something else. Logically, such phishers do not aim to make a high quality of bogus email, rather they aim to take chances in getting potential victims that are very careless. This leads to our hypothesis that say

H8: Phishing emails that include hyperlink will likely to be obfuscated

It is conspicuous from our knowledge if a sales agent tries to sell us a product, it would be followed by the request element to buy the product as well. However, it will not make sense if he tries to sell his product but he requests to buy another company's product. In other words, if we have something to sell, we do not just display our product without asking people's attention to look at our product. For example in phishing email context, phishers may include hyperlink or attachment in the body of the email and also they may request unsuspecting victim to click the hyperlink or to open the attachment. This leads us to two hypotheses which state

H9: Phishing emails that include hyperlink will likely to request to click the hyperlink

H10: Phishing emails that include attachment will likely to request to open the attachment

We sometimes find it suspicious if a person dressed as police officer that does not have a badge carried with him, unless he is a fake police officer. Consequently, a fake police officer may use a fake badge to build up even more “aura of legitimacy”. Evidently, Cialdini suggests the increment of passerby who have stop and stare at the sky by 350 percent with suit and tie instead of casual dress [6]. Hence, we correlate that a person who wears police uniform and a fake badge in the real world context as authority principle and the precence of image in the phishing mail context. Another example, an email that masquerades Apple company, may clone Apple company logo or trademark to its content to increase the chance of potential victim’s response or increase the “believability” if you will. Thus, we hypothesize that

H11: Phishing emails that have authority principle will likely to include an image to its content

Apart from the target analysis, we also investigate the reason why potential victim responds to phisher’s request. Phishing email that implies our account expiration would have scarcity principle because the account itself may very valuable for us and is in danger to be expired or terminated. Therefore, we hypothesize that

H12: There will be a significant association between account related reason and scarcity principle

Similar from the hypothesis H14, it is sensible if a phishing email which contains account related reason such as reset password or security update, may tend to have a hyperlink for the potential victim to be redirected towards phisher’s bogus website or malware. Regardless of the target, based on our initial coding of the dataset we found that account related phishing emails need immediate action greater than other reasons. Therefore, phishers may likely to include a hyperlink to have immediate response from the potential victim. This leads to our hypothesis that say

H13: Phishing emails which have account related reason will likely to have hyperlinks

When a phishing email has document related reason such as review some document reports or court notice, it may tend to impersonate government to make the email sensible enough to persuade potential victim more than other targets. We therefore hypothesize that

H14: Phishing emails which have document related reason will likely targeting government sector

Analogous with the hypothesis **H15**, it is make sense if a phishing email which has document related reason such as reviewing contract agreement or reviewing resolution case, would tend to have a file to be attached. We therefore hypothesize that

H15: Phishing emails which have document related reason will likely to include attachment

We think it is make sense if a phishing email which use HTML to present their email design may tend to increase the attractiveness to the potential victim. Consequently, unsuspected victim may respond to the request just because of the email design is attractive. Therefore, we hypothesize that

H16: Phishing emails which use HTML will have a significant association with likeability principle

DATA AND ANALYSIS

5.1 RESEARCH METHODOLOGY

As we illustrate in [Figure 12](#), we processed our data into several steps. Firstly, we collect our raw data from fraudehelpdesk in the form of suspected phishing email reports. Next, we performed our data categorization and we divided it into three categorization tasks. The next step, we determined what variables are needed for our analysis. Next step, we executed our data classification into these variables, so that we could reconstruct into SPSS readable dataset. Lastly, we conducted our SPSS analysis to answer our hypotheses.

5.1.1 *Raw data collection*

The data gathered from fraudehelpdesk.nl by my supervisor, Elmer Lastdrager MSc. in the form of phishing emails which were reported between august 2013 and december 2013. The data consists of 8444 suspected phishing emails in total that we categorized based on the language, whether the reported phishing email is in Dutch or English language. The data was categorized in the confidential environment, which mean we only analyzed the data in Zilverling building of University of Twente.

5.1.2 *Data categorization*

We manually categorized 8444 suspected phishing emails by sorting all the emails by the subject so that we could tell which emails were being distributed with the exact same content. We then examined individual email which has no or empty subject and determined in which language it was delivered. Initial categorization resulted as follows:

- 7756 suspected phishing emails in Dutch language
- 688 suspected phishing emails in English language

Within 688 suspected phishing emails in English language we further categorized based on phishing, spam and unknown emails. We label this process as 1st precision categorization. Phishing category is determined which email were indeed phishing, spam category is specified which email were spam and unknown category is established by the following guidelines:

Figure 12: Research methodology diagram

- The email which has no content, whether it was removed automatically by antivirus program.
- The email which is presented in the language other than Dutch or English.

The process is resulted as follows:

- 486 phishing emails
- 150 spam emails
- 52 unknown emails

To get a further precision from the 1st precision categorization, we executed 2nd precision categorization within 688 suspected phishing emails in English language. This process is resulted as follows:

- 440 phishing emails
- 180 spam emails
- 50 unknown emails
- 18 legitimate emails

Interestingly, we have 18 legitimate emails that were mistakenly reported as phishes or false positive. Although they are only 18 false positive, this suggest there are still misinterpretation of fraudulent email in our society. From this point we would only code 440 phishing emails to an excel sheet with necessary variables so that we could convert it into SPSS readable file.

5.1.3 Variables establishment

12 Variables were created as part of the methodology processes prior data classification. These variables are explained as follows:

1. *Mail ID* : Unique ID [Scale measurement]
2. *Timestamps*: Implies the date and time when the email is being reported [Scale measurement]
3. *Direct/Indirect*: Whether the phishing email is directly from internal fraudehelpdesk system or from external [0 = Direct, 1= Indirect]
4. *Attachments*: Indicates whether the phishing email has an attachment(s), if so, what kind of attachment
 - a) PDFAttachment [0 = No, 1 = Yes]
 - b) ZIPAttachment [0 = No, 1 = Yes]
 - c) HTMLAttachment [0 = No, 1 = Yes]
5. *Methods*: Implies the inquiry by the phishers in the contents
 - a) ReqOpenAttachment [0 = No, 1 = Yes]
 - b) ReqClickLink [0 = No, 1 = Yes]
 - c) ReqEmailReply [0 = No, 1 = Yes]
 - d) ReqCallingByPhone [0 = No, 1 = Yes]
6. *Contents*: Indicates what elements are included in the body
 - a) ContainHyperlink [0 = No, 1 = Yes]
 - b) UseHTML [0 = No, 1 = Yes]
 - c) IncludeImage [0 = No, 1 = Yes]

7. *ObfuscatedURL*: Specifies whether a phishing email has obfuscatedURL [0 = No, 1 = Yes]
8. *CountMessageReporter*: A counter where the reporter includes extra information [Nominal measurement]
9. *Target*: Determined the target institutions
 - a) *TargetType* [Values can be seen in the appendix]
10. *Reason*: Implies the reason why unsuspected victim must grant the phisher's request
 - a) *ReasonType* [Values can be seen in the appendix]
11. *Cialdini's Principles*: Specifies what principle(s) the phishing email signifies. Coding consideration will be explained on [subsection 5.1.5](#)
 - a) *Reciprocation* [0 = No, 1 = Yes]
 - b) *Consistency* [0 = No, 1 = Yes]
 - c) *SocialProof* [0 = No, 1 = Yes]
 - d) *Likeability* [0 = No, 1 = Yes]
 - e) *Authority* [0 = No, 1 = Yes]
 - f) *Scarcity* [0 = No, 1 = Yes]
12. *CounterSameContents*: A counter that indicates how many phishing emails have exactly the same contents

5.1.4 Data Classification

We classified our data accordingly into our variables. As a result, usable dataset has been made to be statistically analysed. Data classification is conducted in a straightforward way. For example if phishing email has a PDF attachment, we put "1" in our "PDFAttachment" variable. Similarly, if phishing email has a hyperlink in the content, we put "1" in our "ContainHyperlink" variable. Lastly, we conducted synthesization on our data with Cialdini's six principles of persuasion will be discussed in [subsection 5.1.5](#).

5.1.5 Synthesizing Cialdini's principles

Part of our analysis, we tried to synthesize phishing emails dataset with Cialdini's principles titled "The science of persuasion". The decision making and the rationale in this process are achieved based on our perspective of Cialdini's principles as follows:

1. Reciprocation: The norm that obligates individuals to repay in kind what they have received. Return the favor. Adjustment to smaller request [6].
2. Consistency: Public commitment. Where people become psychologically become vested in a decision they have made [71].
3. Social proof: Where people model the behavior of their peer group, role models, important others or because it is generally "fashionable" [71].
4. Likeability: Where people trust and comply with requests from others who they find attractive or are perceived as credible and having special expertise or abilities such as sports figures or actors they like [71].
5. Authority: It can be used to engender fear, where people obey commands to avoid negative consequences such as losing a privilege or something of value, punishment, humiliation or condemnation [71].
6. Scarcity: based on the principle of reactance, where people respond to perceived shortages by placing greater psychological value on perceived scarce items [71].

Reciprocation: When a phisher sends an email containing a message that perceived as a request or obligation towards the recipient to "return the favor". It might be normal for an individual to feel "obligated" to return the favor for things or information that he/she deemed to be valuable. For example in the phishing email context, when PayPal has detected there are suspicious activities on our account, we sometimes believe that PayPal has done a good job in detecting security risk on their system and we feel "obligated" to return the favor of that valuable information. Another example, if the sender gave the information that they have added "extra security" on their system so that we also feel obligated to grant their request.

Consistency: When a phishing email contains a message that perceived to request recipient's "consistency" on a decision they have made. For example in the phishing email context, when a hotel agent asks us to review the payment details of our reservation that we have previously made, we might feel committed or agreed to review the payment details that has been given. Another example, if Facebook gave a link to change your password that you requested previously to change it. It might be not applicable to those who are not requesting password previously, but we believe it will impact to those who are committed to change the password previously.

Social proof: When a phishing email contains an affiliation of other people that they deemed to be "fashionable". For example, when someone tells us that there are a hundreds of other people who use

particular system, so we might want to agree to use it as well just because a lot of other people use it as well. Another example, when Facebook give information that someone wants to be our friend, and we knew who that someone is. We might tend to follow that request and click the link to accept the request.

Likeability: When a phishing email contains a message that attracts recipient to comply the sender's request based the reference on something or someone that likeable for the recipient. Cialdini [1] identified that people usually "trust those they like". For example, if someone is asking us to download and listen to a music that Michael Jackson made, we might be attracted to download and listen to it just because we happen to love Michael Jackson music. It is like someone is asking us to watch a concert and he/she said, "Coldplay will be there", if we are devoted fan of Coldplay, we might find it very interesting. Another example, when a sender gives compliments to us or committed to help us to safeguard our account from the hackers, we tend to think that the sender cares about our safety, which is good for us, and consequently it might attract us to comply with the sender's request.

Authority: When a phishing email contains logo or image or signature or anything that looks like legitimate institutions. It can be used to makes it look trustworthy so that the recipient might accept and obey the sender's request. For example, when an email is presenting somehow authentic looking signature like "Copyright 2013 PayPal, Inc. All rights reserved" or PayPal logo. Cialdini [1] stated authoritative persuasion could be achieved by only presenting "aura of legitimacy". Another example, when the content of the email stated that it is from "System Administrator" asking for password update. It would be not authoritative if only random people asking us to change our password.

Scarcity: When a phishing email contains a message that tells a recipient to react or respond to scarce/turns-into scarce items or things or privileges. For example in the phishing email context, if a sender tells us that he/she will suspend/deactivate/limit our account if not respond to his/her request, we might want to respond to their request because we are worried we will not able to access our account again or in other words our account become scarce or limited.

High level pseudo-code in [Figure 13](#) is made to illustrate our integration of cialdini's principles with the dataset.

5.2 RESULTS

<in progress>

Figure 13: Integration pseudo-code of cialdini's principles

Table 9: Differences phishing webpage vs legitimate website; target: PayPal

No.	What's changed/added?	Details
1	Irregular scripts	<ul style="list-style-type: none"> • Creation of function zzz() contains variables that holds input value from a form <form onsubmit="return zzz()" class=" edit" action="getinfo.php" method="post" name="fox">. • There are 17 script tag in the original paypal, whereas there are only 5 script tags • If... else.. logic is added to manage how a user inputs his information
	Irregular link tag	<ul style="list-style-type: none"> • We are not sure whether the link tag is added by the phisher or it refers to the original paypal with the different source (PayPal has changed its web page from time to time, it means that the source also change periodically) • Most of the links are redirected to pass.php
	Suspicious form	A form used to ask user to submit his creditcard information, upon clicking, it will parse the information to variables hold by zzz() function

2	Html language	Lang=en whereas the original has lang=de
	Country difference	It based on Algeria PayPal country code DZ whereas the original has DE country code
	Irregular scripts	<ul style="list-style-type: none"> • Script to measure anticlickjack is not present. • Script addition clearly stating that it is a hack script at line 91 • s.prop1="p/gen/login-processing"; s.pageName="p/gen/login-processing::_login-processing"; whereas the original has s.prop1="xpt/Marketing_CommandDriven/homepage/MainHome"; and no s.pageName variable • function scOnload() is present in the original whereas it is not present
3	Title differences	It has different title than the original
		Paypal object redirected based on 20101108 whereas in the original phishload database is based on 20120210
	Irregular scripts	<ul style="list-style-type: none"> • Anticlickjack script is not present • New script addition is present which hide from JavaScript-challenged browsers. • More new script addition is present to manage PayPal login flow <script type="text/javascript">PAYPAL.common.loginflow = 'p/gen/login';... • s.prop1="p/gen/login";
	Css object difference	Paypal object redirected based on 20101108
	Suspicious form	It has <form action="websrc.php" name="login_form" method="post"> as user input for PayPal username and password

6	Different title	Italian vs German language
	Suspicious Form	It has <form action="error_login.php" name="login_form" method="post"> which ask for paypal credentials and redirect them to the wrong action
	Irregular scripts	<ul style="list-style-type: none"> • It has script to hide from javascript challenge browser. • It has script <script type="text/javascript">PAYPAL.common.loginflow = 'p/gen/login'; contains malicious operation • s.prop1="p/gen/login"; • It does not have the function scOnload()
	Flash object	It seems that there is an additional div tag at the bottom and I think it contains flash object.
7	URL encoding	It has weird URL encoding inside script tag document.write(unescape(. . . I think the URLencoding inside the document.write is similar with the non URLencoding. So the rest of the result referred to the URLencoding will be similar as well.
	Suspicious form	If I decode the URL encoding, this form is present <form method="post" name="login_form" action="error_logins.php"> The form above exists again in the non encoding html

	Irregular scripts	<ul style="list-style-type: none"> • Script to hide from javascript challenged browser • The script that contains YAHOO.util.Event.addListener also quite different from the original, yet it exists again at the end • The tag <code><noscript>&lt;img src="//paypal.112.207.net/b/ss/paypalglobal/1/H.6-NS/o?pageName=NonJavaScript" height="1" width="1" border="0" alt="" /&gt;</noscript></code> is removed • There is no function <code>scOnload()</code>
8	Different language	Lang=de vs. lang=en
	Suspicious Form	<code><form action="processing.php" name="login_form" method="post"></code> which ask for login email and password
	Irregular scripts	<ul style="list-style-type: none"> • Script to hide from javascript challenged browser • Suspicious script YAHOO.util.Event.addListener
	Flash object	flash object is added at the bottom
9	Title difference	"Log in" title page
	Irregular scripts	Function <code>validateFormOnSubmit(theForm)</code>
	Suspicious Form	<code>form onsubmit="return validateFormOnSubmit(this)" method="post" action="cnd_pay.php"></code>
	Suspicious link tag	All the links are redirect to itself / no absolute URL path
	Based on individual examination I would say that the web page is completely different than the original	
10	Suspicious Form	<code><form action="error_login.php?cmd=_login-run&dispatch=5885d80a13codb1f998ca054efbdf2c29878a435fe324e2511727fbf3e9efcd8" name="login_form" method="post"></code> asking for login email and login password

	Irregular input tag	<ul style="list-style-type: none"> • <code><input type="submit" class="button primary" value="Log In" name="submit.x" /></code> • <code><input type="hidden" name="operating_system" value="Windows" /><input type="hidden" id="flow_name" name="flow_name" value="p/gen/login" /></code> • <code><input type="hidden" id="bp_ks2" name="bp_ks2" /><input type="hidden" id="bp_ks3" name="bp_ks3" /><input type="hidden" name="flow_name" value="p/gen/login" /></code>
	Irregular scripts	<ul style="list-style-type: none"> • Script to hide from javascript challenged browser • <code>s.prop1="p/gen/login";</code> • no function <code>scOnload()</code>
	Flash object	flash object is added at the bottom

11	Irregular scripts	<ul style="list-style-type: none"> • <code>src="/js/lib/yui/animation.js</code> • script anticlickjack removed • script PAYPAL.util.lazyLoadRoot removed • great amount of scripts are removed • suspicious script <code><script type="text/javascript">if(typeof PAYPAL != 'undefined'){ PAYPAL.core.Navigation.init(); }</script> </div></code> • suspicious script <code>s.prop1="p/gen/login-processing";</code> • function <code>scOnload</code> removed • suspicious script <code>setTimeout("location.href = . . .</code> at the bottom
12	Irregular input	<ul style="list-style-type: none"> • <code><input type="hidden" name="flow_name" value="p/gen/login" /></code> • <code><input type="hidden" value="ok" name="login_cmd" /></code> • <code><input type="hidden" value="" name="login_params" /></code>
	Irregular scripts	<ul style="list-style-type: none"> • <code><script src="files/globaloo.js" type="text/javascript"></code> • script that hides from javascript challenged browser • anticlickjack script is removed • <code><script src="files/pp_jscod.js" type="text/javascript"></script></code> • <code>s.prop1="p/gen/login";</code> • function <code>scOnload</code> removed

	Suspicious Form	<code><form action="" name="login_form" method="post"></code> which ask user input for login credential
	Suspicious link	some of the links are redirected to itself / not absolute URL path
	Flash object	flash object is added at the bottom
15	Irregular input	<code><input type="hidden" name="flow_name" value="p/gen/login" /> • <input type="hidden" value="" name="login_cmd" /><input type="hidden" value="" name="login_params" /></fieldset></code>
	Suspicious form	<code><form action="error_login.php?cmd=_login-run&dispatch=5885d80a13codb1f998ca054efbdf2c29878a435fe324eec2511727fbf3e9efcd8" name="login_form" method="post"></code> that asks login credential
	Irregular scripts	<ul style="list-style-type: none"> • script that hides from javascript challenged browser • anticlickjack script is removed • suspicious script <code><script type="text/javascript">if(typeof PAYPAL != 'undefined'){ PAYPAL.core.Navigation.init(); }</script></code> • suspicious script <code><script type="text/javascript">PAYPAL.common.loginflow = 'p/gen/login';</code> • <code>s.prop1="p/gen/login";</code> • function <code>scOnload</code> is removed
	Flash object	flash added at the bottom (perhaps it is from the latest legitimate paypal website)
16	Suspicious form	<code><form action="Submit.php" name="login_form" method="post"></code>

	Irregular scripts	<ul style="list-style-type: none"> • script that hides from javascript challenge browser • YAHOO.util.Event.addListener script • s.prop1="xpt/Marketing_CommandDriven/homepage/IndividualsHome"; • function scOnload() is removed • YUE.addListener script at the bottom
	Irregular links	href="#content
17	Suspicious Form	<form action="processing.php" name="login_form" method="post">
	Irregular scripts	script that hides from javascript challenge browsers function scOnload is removed
	Irregular links	href="#"
18	Irregular input	<ul style="list-style-type: none"> • <input type="hidden" name="flow_name" value="p/gen/login" /> • <input type="hidden" value="" name="login_cmd" /> • <input type="hidden" value="" name="login_params" />
	Irregular from	<form action="error_login.php" name="login_form" method="post">
	Irregular script	<ul style="list-style-type: none"> • script that hides from javascript challenge browsers • anticlickjack script removed • PAYPAL.tns.loginflow script • PAYPAL.common.loginflow = 'p/gen/login' added • s.prop1="p/gen/login"; • function scOnload is removed
	Flash object	Flash added at the bottom

19	Irregular script	<ul style="list-style-type: none"> • <code><script type="text/javascript"></code> if (parent.frames.length > 0) {top.location.replace(document.location); }</script> • Script that hides from javascript challenge browsers • <code><script type="text/javascript">PAYPAL.common.loginflow = 'p/gen/login';</code> • <code>s.prop1="p/gen/login";</code> • function scOnload is removed
	Irregular links	<code><li class="login">Einloggen</code>
	Suspicious form	<code><form action="websrc.php" name="login_form" method="post"></code>
	Irregular input	<code><input type="hidden" name="flow_name" value="p/gen/login" /></code>
	Flash object	flash added at the bottom
20	Suspicious form	<code><form action="asu.php" name="login" method="POST"></code>
	Irregular link	all the links are redirected to itself
	Irregular script	<code><script type="text/javascript" language="JavaScript"></code>
	Based on individual examination I would say that the web page is completely different than the original
